# Sources

In this lecture I adopt slides from the following sources:

- Varun Kanade, University of Oxford, PCA and MDS
- Tibshirani, Stanford University, NMF
- Tibshirani, Stanford University, Isomap
- Tibshirani, Stanford University, Principle Components
- Hastie, Tibshirani, and Friedman, Chapter 14.5

## Supervised Learning: Summary

- ▶ Training data is of the form  $\langle (\mathbf{x}_i, y_i) \rangle$  where  $\mathbf{x}_i$  are features and  $y_i$  is target
- ▶ We formulate a model: generative or discriminative
- ▶ Choose a suitable training criterion (loss function, maximum likelihood)
- ▶ Use optimisation procedure to learn parameters
- ▶ Use regularization or other techniques to reduce overfitting
- ▶ Use trained classifier to predict targets/labels on unseen  $\mathbf{x}_{\text{new}}$

# Unsupervised Learning

Training data is of the form  $\mathbf{x}_1, \dots, \mathbf{x}_N$

Infer properties about the data

- ▶ Search: Identify patterns in data
- ▶ Density Estimation: Learn the underlying distribution generating data
- ▶ Clustering: Group similar points together
- ▶ **Today**: Dimensionality Reduction

# Motivation

- Visualization
- Data Compression
- Feature Engineering

## PCA: Maximum Variance View

PCA is a *linear* dimensionality reduction technique

Find the directions of maximum variance in the data  $\langle (\mathbf{x}_i) \rangle_{i=1}^N$

Assume that data is centered, *i.e.*,  $\sum_i \mathbf{x}_i = \mathbf{0}$

Find a set of orthogonal vectors  $\mathbf{v}_1, \dots, \mathbf{v}_k$

- ▶ The first principal component (PC)  $\mathbf{v}_1$  is the direction of largest variance
- ▶ The second PC  $\mathbf{v}_2$  is the direction of largest variance orthogonal to  $\mathbf{v}_1$
- ▶ The  $i^{th}$  PC  $\mathbf{v}_i$  is the direction of largest variance orthogonal to  $\mathbf{v}_1, \dots, \mathbf{v}_{i-1}$

$\mathbf{V}_{D \times k}$  gives projection

$$\mathbf{z}_i = \mathbf{V}^T \mathbf{x}_i \quad \text{for datapoint } \mathbf{x}_i$$

$$\mathbf{Z} = \mathbf{XV} \quad \text{for entire dataset}$$

## PCA: Maximum Variance View

We are given i.i.d. data  $\langle (\mathbf{x}_i) \rangle_{i=1}^N$ ; data matrix  $\mathbf{X}$

Want to find  $\mathbf{v}_1 \in \mathbb{R}^D$ ,  $\|\mathbf{v}_1\| = 1$ , that maximizes  $\|\mathbf{X}\mathbf{v}_1\|^2$

Let  $\mathbf{z} = \mathbf{X}\mathbf{v}_1$ , so  $z_i = \mathbf{x}_i \cdot \mathbf{v}_1$ .

We wish to find  $\mathbf{v}_1$  so that  $\sum_{i=1}^N z_i^2$  is maximised.

$$\begin{aligned}\sum_{i=1}^N z_i^2 &= \mathbf{z}^T \mathbf{z} \\ &= \mathbf{v}_1^T \mathbf{X}^T \mathbf{X} \mathbf{v}_1\end{aligned}$$

The maximum value attained by  $\mathbf{v}_1^T \mathbf{X}^T \mathbf{X} \mathbf{v}_1$  for  $\|\mathbf{v}_1\| = 1$  is the largest eigenvalue of  $\mathbf{X}^T \mathbf{X}$ .

The  $\text{argmax}$  is the corresponding eigenvector  $\mathbf{v}_1$ .

Find  $\mathbf{v}_2, \mathbf{v}_3, \dots, \mathbf{v}_k$  that are all successively orthogonal to previous directions and maximise (as yet unexplained variance)

## PCA: Best Reconstruction

We have i.i.d. data  $\langle (\mathbf{x}_i) \rangle_{i=1}^N$ ; data matrix  $\mathbf{X}$

Find a  $k$ -dimensional linear projection that best **represents** the data

Suppose  $\mathbf{V}_k \in \mathbb{R}^{D \times k}$  is such that columns of  $\mathbf{V}_k$  are orthogonal

Project data  $\mathbf{X}$  on to subspace defined by  $\mathbf{V}$

$$\mathbf{Z} = \mathbf{X}\mathbf{V}_k$$

Minimize reconstruction error

$$\sum_{i=1}^N \|\mathbf{x}_i - \mathbf{V}_k \mathbf{V}_k^T \mathbf{x}_i\|^2$$

# Principal Component Analysis (PCA)

## Equivalence between the Two Objectives: One PC Case

Let  $\mathbf{v}_1$  be the direction of projection

The point  $\mathbf{x}$  is mapped to  $\tilde{\mathbf{x}} = (\mathbf{v}_1 \cdot \mathbf{x})\mathbf{v}_1$ , where  $\|\mathbf{v}_1\| = 1$

### Maximum Variance

Find  $\mathbf{v}_1$  that maximises  $\sum_{i=1}^N (\mathbf{v}_1 \cdot \mathbf{x}_i)^2$

### Best Reconstruction

Find  $\mathbf{v}_1$  that minimises:

$$\begin{aligned}\sum_{i=1}^N \|\mathbf{x}_i - \tilde{\mathbf{x}}_i\|^2 &= \sum_{i=1}^N \left( \|\mathbf{x}_i\|^2 - 2(\mathbf{x}_i \cdot \tilde{\mathbf{x}}_i) + \|\tilde{\mathbf{x}}_i\|^2 \right) \\ &= \sum_{i=1}^N \left( \|\mathbf{x}_i\|^2 - 2(\mathbf{v}_1 \cdot \mathbf{x}_i)^2 + (\mathbf{v}_1 \cdot \mathbf{x}_i)^2 \|\mathbf{v}_1\|^2 \right) \\ &= \sum_{i=1}^N \|\mathbf{x}_i\|^2 - \sum_{i=1}^N (\mathbf{v}_1 \cdot \mathbf{x}_i)^2\end{aligned}$$

So the **same**  $\mathbf{v}_1$  satisfies the two objectives

## Finding Principal Components: SVD

Let  $\mathbf{X}$  be the  $N \times D$  data matrix

Pair of singular vectors  $\mathbf{u} \in \mathbb{R}^N$ ,  $\mathbf{v} \in \mathbb{R}^D$  and singular value  $\sigma \in \mathbb{R}^+$  if

$$\sigma \mathbf{u} = \mathbf{X} \mathbf{v} \quad \text{and} \quad \sigma \mathbf{v} = \mathbf{X}^T \mathbf{u}$$

$\mathbf{v}$  is an eigenvector of  $\mathbf{X}^T \mathbf{X}$  with eigenvalue  $\sigma^2$

$\mathbf{u}$  is an eigenvector of  $\mathbf{X} \mathbf{X}^T$  with eigenvalue  $\sigma^2$

## Finding Principal Components: SVD

$$\mathbf{X} = \mathbf{U}\mathbf{\Sigma}\mathbf{V}^T \text{ (say } N > D\text{)}$$

**Thin SVD:**  $\mathbf{U}$  is  $N \times D$ ,  $\mathbf{\Sigma}$  is  $D \times D$ ,  $\mathbf{V}$  is  $D \times D$ ,  $\mathbf{U}^T\mathbf{U} = \mathbf{V}^T\mathbf{V} = \mathbf{I}_D$

$\mathbf{\Sigma}$  is diagonal with  $\sigma_1 \geq \sigma_2 \geq \dots \geq \sigma_D \geq 0$

The first  $k$  principal components are first  $k$  columns of  $\mathbf{V}$

**Full SVD:**  $\mathbf{U}$  is  $N \times N$ ,  $\mathbf{\Sigma}$  is  $N \times D$ ,  $\mathbf{V}$  is  $D \times D$ .  $\mathbf{V}$  and  $\mathbf{U}$  are orthonormal matrices

## Algorithm for finding PCs (when $N > D$ )

Constructing the matrix  $\mathbf{X}^T \mathbf{X}$  takes time  $O(D^2 N)$

Eigenvectors of  $\mathbf{X}^T \mathbf{X}$  can be computed in time  $O(D^3)$

Iterative methods to get top  $k$  singular (right) vectors directly:

- ▶ Initiate  $\mathbf{v}^0$  to be random unit norm vector
- ▶ Iterative Update:
  - ▶  $\mathbf{v}^{t+1} = \mathbf{X}^T \mathbf{X} \mathbf{v}^t$
  - ▶  $\mathbf{v}^{t+1} = \mathbf{v}^{t+1} / \|\mathbf{v}^{t+1}\|$until (approximate) convergence
- ▶ Update step only takes  $O(ND)$  time (compute  $\mathbf{X} \mathbf{v}^t$  first, then  $\mathbf{X}^T (\mathbf{X} \mathbf{v}^t)$ )
- ▶ This gives the singular vector corresponding to the largest singular value
- ▶ Subsequent singular vectors obtained by choosing  $\mathbf{v}^0$  orthogonal to previously identified singular vectors (this needs to be done at each iteration to avoid numerical errors creeping in)

## Algorithm for finding PCs (when $D \gg N$ )

Constructing the matrix  $\mathbf{X}\mathbf{X}^T$  takes time  $O(N^2D)$

Eigenvectors of  $\mathbf{X}\mathbf{X}^T$  can be computed in time  $O(N^3)$

The eigenvectors give the 'left' singular vectors,  $\mathbf{u}_i$  of  $\mathbf{X}$

To obtain  $\mathbf{v}_i$ , we use the fact that  $\mathbf{v}_i = \sigma^{-1}\mathbf{X}^T\mathbf{u}_i$

Iterative method can be used directly as in the case when  $N > D$

## PCA: Reconstruction Error

We have thin SVD:  $\mathbf{X} = \mathbf{U}\mathbf{\Sigma}\mathbf{V}^T$

Let  $\mathbf{V}_k$  be the matrix containing first  $k$  columns of  $\mathbf{V}$

Projection on to  $k$  PCs:  $\mathbf{Z} = \mathbf{X}\mathbf{V}_k = \mathbf{U}_k\mathbf{\Sigma}_k$ , where  $\mathbf{U}_k$  is the matrix of the first  $k$  columns of  $\mathbf{U}$  and  $\mathbf{\Sigma}_k$  is the  $k \times k$  diagonal submatrix for  $\mathbf{\Sigma}$  of the top  $k$  singular values

Reconstruction:  $\tilde{\mathbf{X}} = \mathbf{Z}\mathbf{V}_k^T = \mathbf{U}_k\mathbf{\Sigma}_k\mathbf{V}_k^T$

$$\text{Reconstruction error} = \sum_{i=1}^N \|\mathbf{x}_i - \mathbf{V}_k\mathbf{V}_k^T\mathbf{x}_i\|^2 = \sum_{j=k+1}^D \sigma_j^2$$

This follows from the following calculations:

$$\begin{aligned}\mathbf{X} &= \mathbf{U}\mathbf{\Sigma}\mathbf{V}^T = \sum_{j=1}^D \sigma_j \mathbf{u}_j \mathbf{v}_j^T & \tilde{\mathbf{X}} &= \mathbf{U}_k\mathbf{\Sigma}_k\mathbf{V}_k^T = \sum_{j=1}^k \sigma_j \mathbf{u}_j \mathbf{v}_j^T \\ \|\mathbf{X} - \tilde{\mathbf{X}}\|_F &= \sum_{j=k+1}^D \sigma_j^2\end{aligned}$$

# Reconstruction of an Image using PCA

$K = 2$

$K = 5$

$K = 20$

$K = 50$

$K = 100$

$K = 300$

## How many principal components to pick?

Look for an 'elbow' in the curve of reconstruction error vs # PCs

## Section 2

### Linear Model View of PCA

# Handwritten Digits Data (MNIST Data)

**FIGURE 14.22.** A sample of 130 handwritten 3's shows a variety of writing styles.

## Low Rank Linear Approximation

$$\begin{aligned}\hat{f}(\lambda) &= \bar{x} + \lambda_1 v_1 + \lambda_2 v_2 \\ &= \boxed{\text{3}} + \lambda_1 \cdot \boxed{\text{3}} + \lambda_2 \cdot \boxed{\text{3}}\end{aligned}$$

# PCA Representation

**FIGURE 14.23.** (Left panel:) the first two principal components of the handwritten threes. The circled points are the closest projected images to the vertices of a grid, defined by the marginal quantiles of the principal components. (Right panel:) The images corresponding to the circled points. These show the nature of the first two principal components.

## Are PCs independent? continued

## Section 3

### Example Applications of PCA

# Application: Eigenfaces

A popular application of PCA for face detection and recognition is known as **Eigenfaces**

- ▶ **Face detection:** Identify faces in a given image
- ▶ **Face Recognition:** Classification (or search) problem to identify a certain person

## Application: Eigenfaces

PCA on a dataset of face images. Each principal component can be thought of as being an 'element' of a face.

Source: <http://vismod.media.mit.edu/vismod/demos/facerec/basic.html>

## Application: Eigenfaces

**Detection:** Each patch of the image can be checked to identify whether there is a face in it

**Recognition:** Map all faces in terms of their principal components. Then use some distance measure on the projections to find faces that are most like the input image.

### Why use PCA for face detection?

- ▶ Even though images can be large, we can use the  $D \gg N$  approach to be efficient
- ▶ The final model (the PCs) can be quite compact, can fit on cameras, phones
- ▶ Works very well given the simplicity of the model

## Application: Latent Semantic Analysis

$\mathbf{X}$  is an  $N \times D$  matrix,  $D$  is the size of dictionary

$\mathbf{x}_i$  is a vector of word counts (bag of words)

Reconstruction using  $k$  eigenvectors  $\mathbf{X} \approx \mathbf{Z}\mathbf{V}_k^\top$ , where  $\mathbf{Z} = \mathbf{X}\mathbf{V}_k$

$\langle \mathbf{z}_i, \mathbf{z}_j \rangle$  is probably a better notion of similarity than  $\langle \mathbf{x}_i, \mathbf{x}_j \rangle$

Non-negative matrix factorisation has more natural interpretation, but is harder to compute

## Section 4

### Kernel PCA

## PCA: Beyond Linearity

## PCA: Beyond Linearity

## PCA: Beyond Linearity

## PCA: Beyond Linearity

# Projection: Linear PCA

# Projection: Kernel PCA

## Kernel PCA

Suppose our original data is, for example,  $\mathbf{x} \in \mathbb{R}^2$

We could perform degree 2 polynomial basis expansion as:

$$\phi(\mathbf{x}) = \left[ 1, \sqrt{2}x_1, \sqrt{2}x_2, x_1^2, x_2^2, \sqrt{2}x_1x_2 \right]^\top$$

Recall that we can compute the inner products  $\phi(\mathbf{x}) \cdot \phi(\mathbf{x}')$  efficiently using the **kernel trick**

$$\begin{aligned}\phi(\mathbf{x}) \cdot \phi(\mathbf{x}') &= 1 + 2x_1x'_1 + 2x_2x'_2 + x_1^2(x'_1)^2 + x_2^2(x'_2)^2 + 2x_1x_2x'_1x'_2 \\ &= (1 + x_1x_2 + x'_1x'_2)^2 = (1 + \mathbf{x} \cdot \mathbf{x}')^2 =: \kappa(\mathbf{x}, \mathbf{x}')\end{aligned}$$

## Kernel PCA

Suppose we use the feature map:  $\phi : \mathbb{R}^D \rightarrow \mathbb{R}^M$

Let  $\phi(\mathbf{X})$  be the  $N \times M$  matrix

We want find the singular vectors of  $\phi(\mathbf{X})$  (eigenvectors of  $\phi(\mathbf{X})^\top \phi(\mathbf{X})$ )

However, in general  $M \gg N$  (in fact  $M$  could be infinite for some kernels)

Instead we'll find the eigenvectors of  $\phi(\mathbf{X})\phi(\mathbf{X})^\top$ , the kernel matrix

## Kernel PCA

Recall that the kernel matrix is:

$$\mathbf{K} = \phi(\mathbf{X})\phi(\mathbf{X})^T = \begin{bmatrix} \kappa(\mathbf{x}_1, \mathbf{x}_1) & \kappa(\mathbf{x}_1, \mathbf{x}_2) & \cdots & \kappa(\mathbf{x}_1, \mathbf{x}_N) \\ \kappa(\mathbf{x}_2, \mathbf{x}_1) & \kappa(\mathbf{x}_2, \mathbf{x}_2) & \cdots & \kappa(\mathbf{x}_2, \mathbf{x}_N) \\ \vdots & \vdots & \ddots & \vdots \\ \kappa(\mathbf{x}_N, \mathbf{x}_1) & \kappa(\mathbf{x}_N, \mathbf{x}_2) & \cdots & \kappa(\mathbf{x}_N, \mathbf{x}_N) \end{bmatrix}$$

Let  $\mathbf{u} \in \mathbb{R}^N$  be an eigenvector of  $\mathbf{K}$ , (left singular vector of  $\phi(\mathbf{X})$ )

The corresponding principal component  $\mathbf{v} \in \mathbb{R}^M$  is  $\sigma^{-1}\phi(\mathbf{X})^T\mathbf{u}$

We won't express  $\mathbf{v}$  explicitly, instead we can compute projections of a new datapoint  $\mathbf{x}_{\text{new}}$  on to the principal component  $\mathbf{v}$  using the kernel function:

$$\phi(\mathbf{x}_{\text{new}})^T\mathbf{v} = \sigma^{-1}\phi(\mathbf{x}_{\text{new}})^T\phi(\mathbf{X})^T\mathbf{u} = \sigma^{-1}[\kappa(\mathbf{x}_{\text{new}}, \mathbf{x}_1), \kappa(\mathbf{x}_{\text{new}}, \mathbf{x}_2), \cdots, \kappa(\mathbf{x}_{\text{new}}, \mathbf{x}_N)]\mathbf{u}$$

So in order to compute projections onto principal components we do not need to store the principal components explicitly!

## Kernel PCA

For PCA, we assumed that the datamatrix  $\mathbf{X}$  is centered, *i.e.*,  $\sum_i \mathbf{x}_i = \mathbf{0}$

However, this is not the case for the matrix  $\phi(\mathbf{X})$

Instead we can consider:

$$\tilde{\phi}(\mathbf{x}_i) = \phi(\mathbf{x}_i) - \frac{1}{N} \sum_{k=1}^N \phi(\mathbf{x}_k)$$

The corresponding matrix  $\tilde{\mathbf{K}}$  is given by the entries

$$\tilde{K}_{ij} = \kappa(\mathbf{x}_i, \mathbf{x}_j) - \frac{1}{N} \sum_{l=1}^N \kappa(\mathbf{x}_i, \mathbf{x}_l) - \frac{1}{N} \sum_{l=1}^N \kappa(\mathbf{x}_j, \mathbf{x}_l) + \frac{1}{N^2} \sum_{k=1}^N \sum_{l=1}^N \kappa(\mathbf{x}_l, \mathbf{x}_k)$$

Succintly, if  $\mathbf{O}$  is the matrix of all with every entry  $1/N$ , *i.e.*,  $\mathbf{O} = \mathbf{1}\mathbf{1}^T/N$

$$\tilde{\mathbf{K}} = \mathbf{K} - \mathbf{O}\mathbf{K} - \mathbf{K}\mathbf{O} + \mathbf{O}\mathbf{K}\mathbf{O}$$

To perform kernel PCA, we need to find the eigenvectors of  $\tilde{\mathbf{K}}$

## Projection: PCA vs Kernel PCA

## Kernel PCA Applications

- ▶ Kernel PCA is not necessarily very useful for visualisation
- ▶ Also, kernel PCA does not directly give a useful way to construct a low-dimensional reconstruction of the original data
- ▶ Most powerful uses of kernel PCA are in other machine learning applications
- ▶ After kernel PCA preprocessing, we may get higher accuracy for classification, clustering, *etc.*

## PCA Summary

**Algorithm:** We've expressed PCA as SVD of data matrix  $\mathbf{X}$

Equivalently, we can use eigendecomposition of the matrix  $\mathbf{X}^T \mathbf{X}$

**Running Time:**  $O(NDk)$  to compute  $k$  principal components (avoid computing the matrix  $\mathbf{X}^T \mathbf{X}$ )

PCs are uncorrelated, but there may be non-linear (higher-order) effects

PCA depends on **scale** or units of measurement; it may be a good idea to **standardize** data

PCA is sensitive to outliers

PCA can be kernelised: Useful as preprocessing for further ML applications, rather than visualisation

## Section 5

### Other Dimension Reduction Techniques

# Non-negative matrix factorization (NMF)

## Non-negative matrix factorization

- Lee & Seung (1999)
- like principal components (SVD), but data and components are assumed to be non-negative
- Model

$$\mathbf{X} \approx \mathbf{WH}$$

where  $X$  is  $n \times p$ ,  $W$  is  $n \times r$ ,  $H$  is  $r \times p$ ,  $r \leq p$ .

- we assume  $X_{ij}, W_{ij}, H_{ij} \geq 0$ .
- criterion: minimize

$$L(\mathbf{W}, \mathbf{H}) = \sum_i \sum_u [X_{iu} \log(WH)_{iu} - (WH)_{iu}]$$

This is the log-likelihood for the model  $X_{iu} \sim \text{Poisson}(WH)_{iu}$ .

**Big problem!**

See Donoho and Stodden (2004): “When does non-negative matrix factorization give a correct decomposition into parts?” Advances in Neural Information Processing Systems, 17, 2004

- columns of  $W$  are not required to be orthogonal, as in principal components
- solution is not unique (even when  $X = WH$  holds exactly):  
can choose for columns of  $W$  any vectors in gap between axes and the data
- this limits its utility in practice

# Non-linear Dimension Reduction

## Non-linear dimension reduction

- ISOMAP: Tenenbaum, de Silva & Langford (2000)
- Local linear embedding: Roweis & Saul (2000)
- Local MDS: Chen (2006)
- all three methods try to map points on a high-dimensional non-linear manifold to a lower dimensional set of coordinates
- useful for problems where signal-to-noise ratio is very high (e.g. a physical system). May not be useful for observational data

# Autoencoders

# Supervised Linear Dimension Reduction

- Partial Least Squares
- Linear Discriminant Analysis
